Javascript Variables & Objects

https://slides.com/concise/js/

concise JavaScript

A concise and accurate JavaScript tutorial/notes written for those entering the JavaScript world for the first time but already have experience with other languages

Some slides extracted from above reference

Basic Concepts About Variables

Definition

A variable is a named container for a value

The *name* that refers to a variable is sometime called *an identifier*

```
var x;
var y = "Hello JS!";
var z;
```

These red boxes are variables, and each of them has a name (identifier)

Any JavaScript value can be contained within these boxes

```
var x;
var y = "Hello JS!";
var z;
z = false;
z = 101;
```

We can *assign* another *value* to a variable later after its creation

Curly-brace blocks do not introduce new variable scopes in JavaScript

```
// What is i, $, p, and q afterwards?
var i = -1;
for (var i = 0; i < 10; i += 1) {
    var $ = -i;
  (true) {
    var p = 'F00';
} else {
    var q = 'BAR';
// Check the next slide for an answer...
```

The code in previous page actually works like this one:

```
var i, $, p, q; // all undefined
i = -1;
for (i = 0; i < 10; i += 1) {
    $ = -i;
   (true) {
                           When the program runs, all variable declarations
    p = 'FOO';
                           are moved up to the top of the current scope.
} else {
    q = 'BAR';
// i=10, $=-9, p='FOO', q=undefined
```

let & const do NOT behave like var

They introduce 'Block Scoped' variables that:

- cannot be redefined
- can only be used in the scope they are declared in

I.E. They closely match the way Java Local Variables are scoped.

const & let are Block Scoped

```
const greeting = 'hello';
{
  const greeting = 'howdy';
  console.log(greeting);
}
console.log(greeting);
```

 2 variables called greeting defined in two separate scopes

var is not Block Scoped

```
var greeting = 'hello';
{
  var greeting = 'howdy';
  console.log(greeting);
}
console.log(greeting);
```

- 1 variable called greeting defined.
- Second greeting is *Hoisted* to the outer scope

let & const VS var

Because they are more predictable, we will always prefer **let** & **const** to **var**

Reserved Words

Some keywords can not be used as variable names:

null true false break do instanceof typeof case else new var catch finally return void continue for switch while debugger function this with default if throw delete in try class enum extends super const export import

implements let private public yield interface package protected static

We don't need to remember them all. Just be aware of the possible cause for some SyntaxError exceptions in our program.

Basic Concepts About Values & Types

Definition

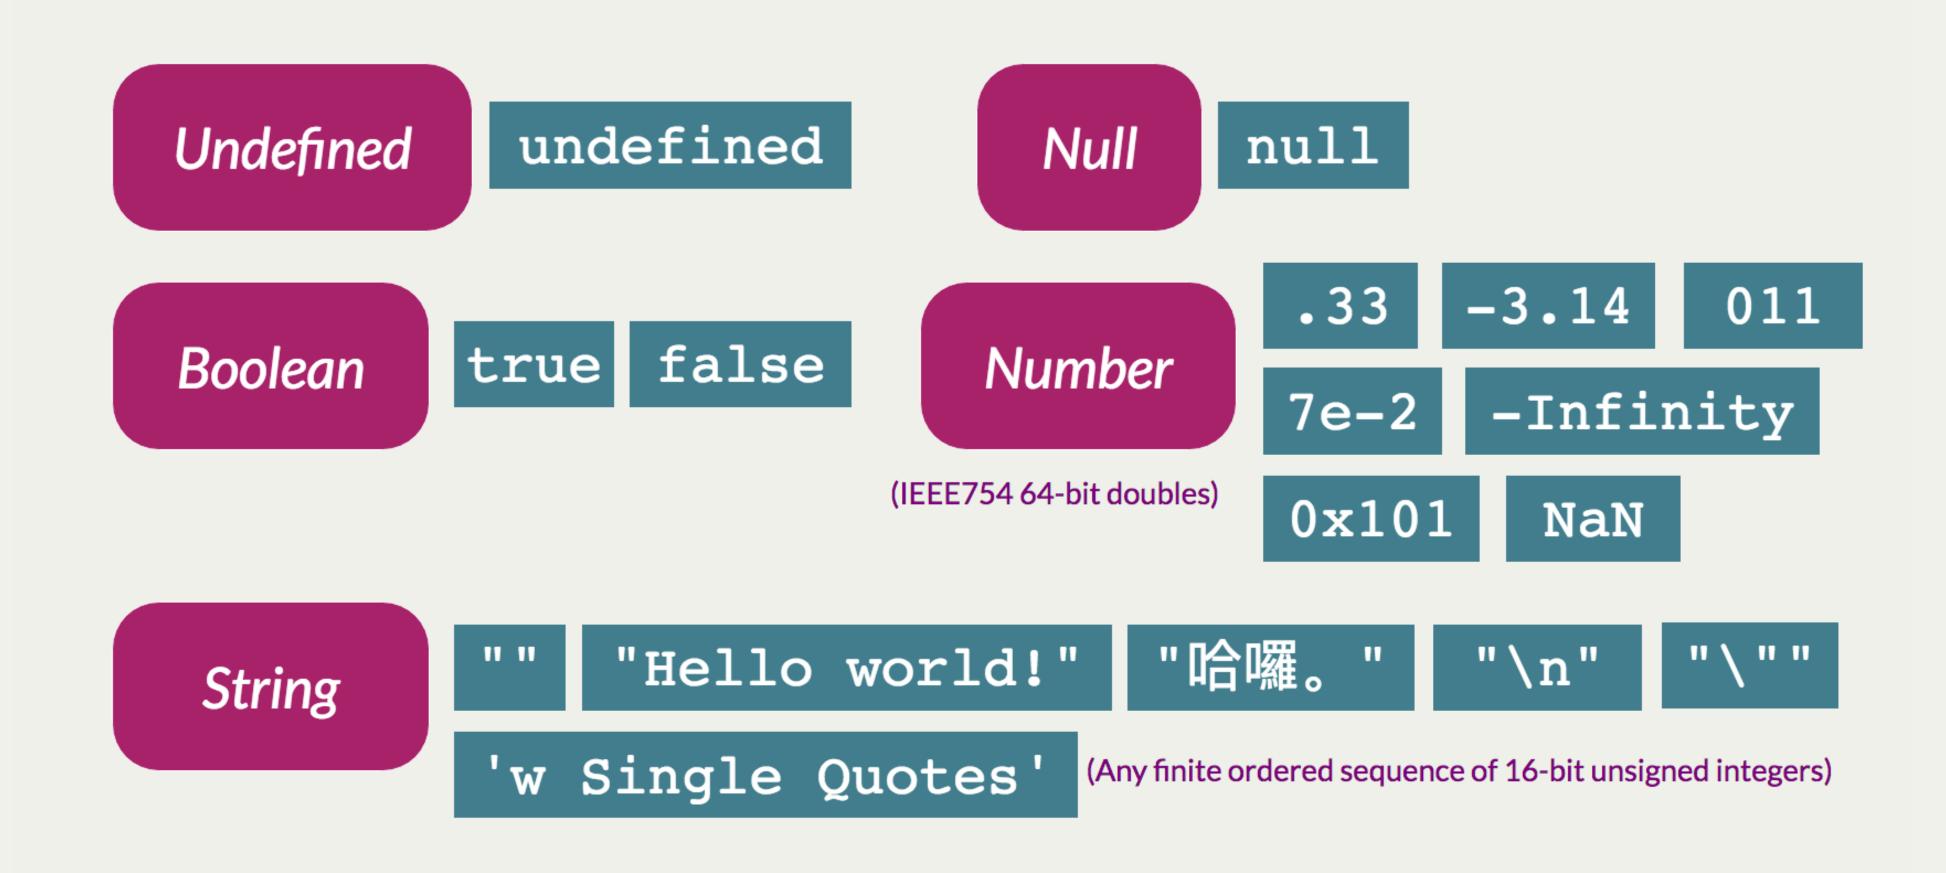

A value represents the most basic data we can deal with

value

A type is a *set* of data values, and there are exactly 6 types

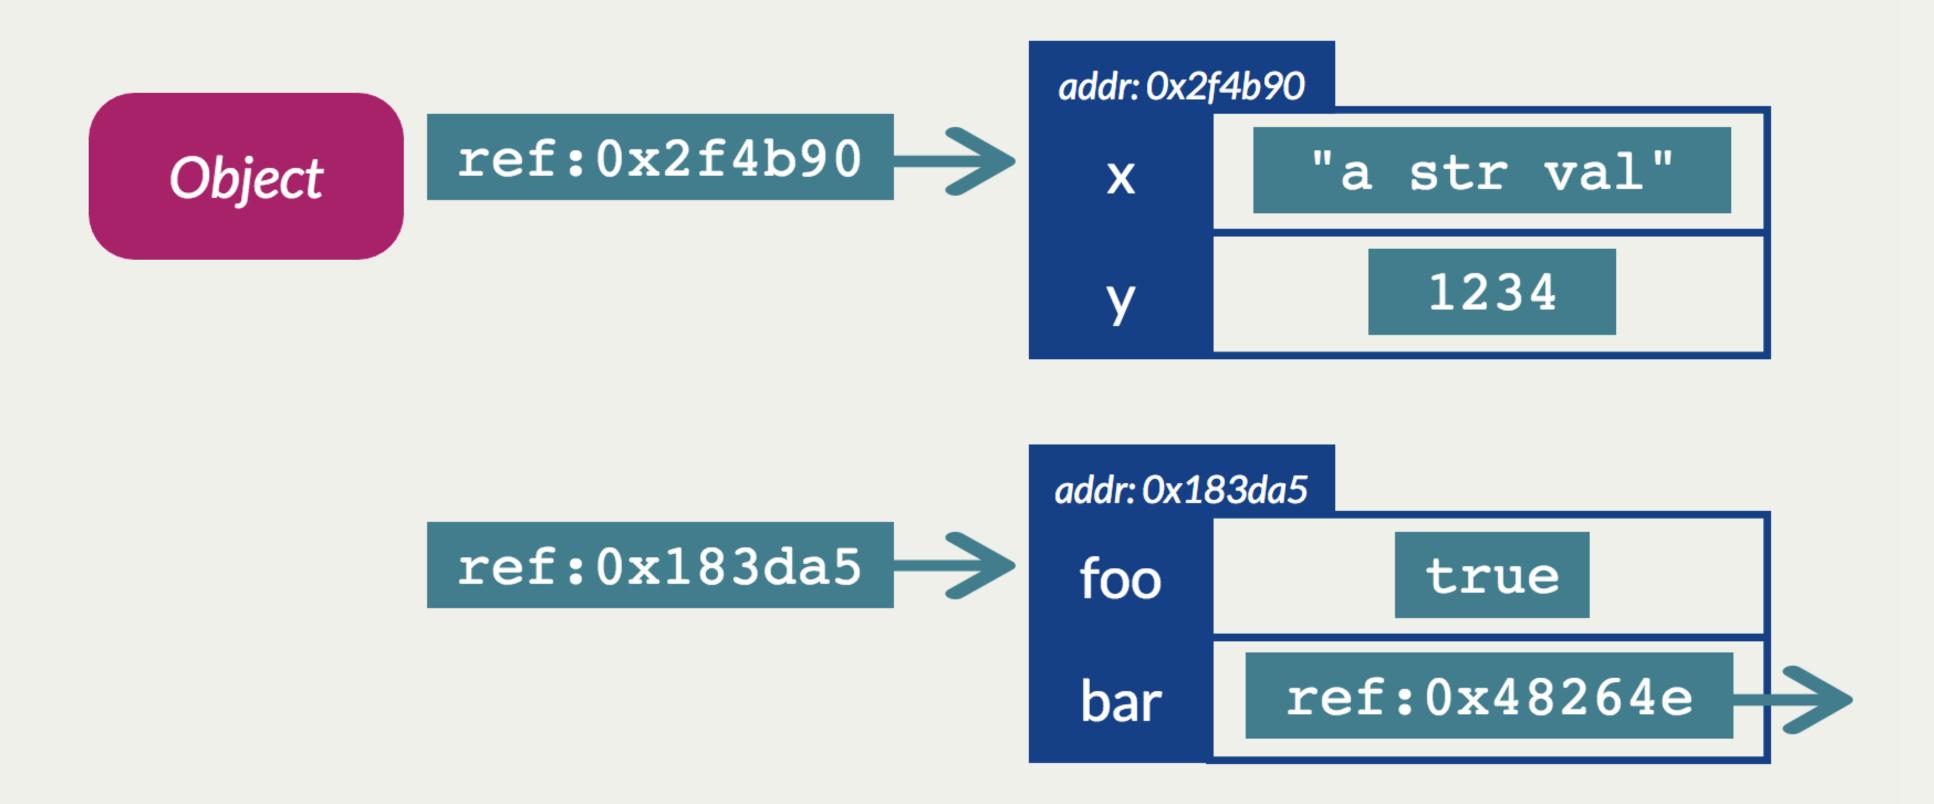

```
Type : { v1 , v2 , v3 }
```

There are 5 primitive (non-Object) types

Any value here is called a primitive value

And then there is the "Object" type

Any value of this type is a reference to some "object"; sometimes we would simply call such value an object

Definition

An object is a collection of *properties*

A property is a named container for a *value* w/ some additional attributes

Definition

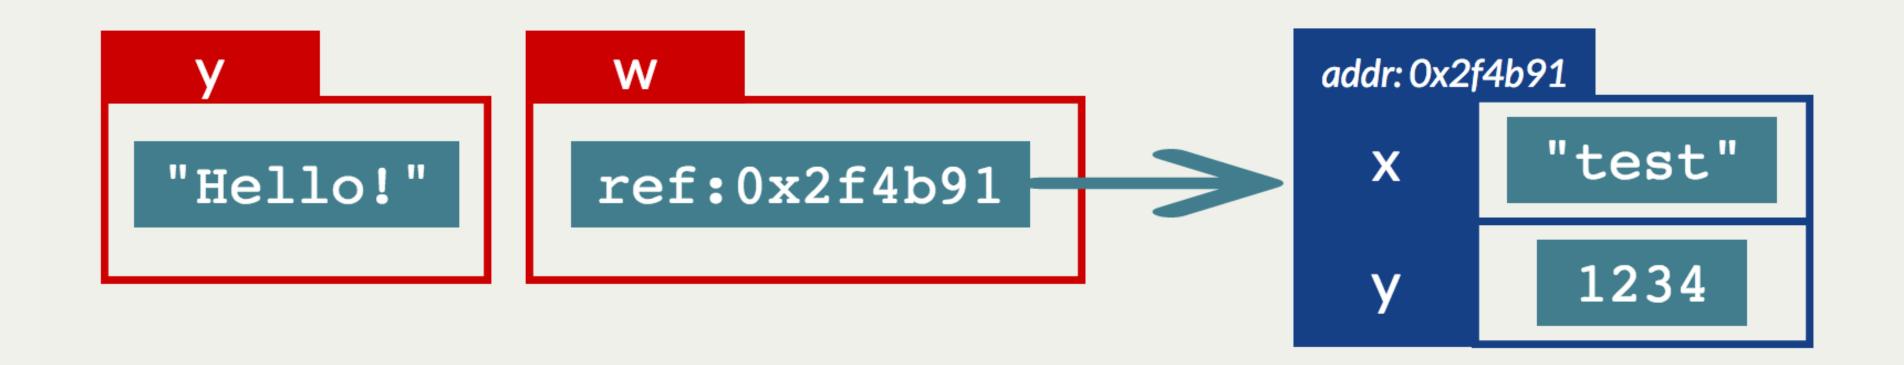

The name of a property is called a key; thus, an object can be considered as a collection of key-value pairs.

There are similar concepts in other programming languages, e.g., Map, Dictionary, Associative Array, Symbol Table, Hash Table, ...

To Refer To A Value

- Literal notation for the value
- Expression involving a variable or a property within some object to get the value indirectly
- More complex expression involving function *calls* and *operators*

A "variable" vs a "property" in an object

```
// Value containers
var y = "Hello!";
var w = {
    x: "test",
    y: 1234
};
```

```
// To get the values
  // "Hello!"
w; // (the object ref)
w.x; // "test"
w['x']; // "test"
       // 1234
W.Y;
w["y"]; // 1234
```

Object Initialiser (Object Literal)

The notation using a pair of curly braces to *initialize* a new JavaScript object.

```
var w = {
    x: "test",
    y: 1234,
    z: {},
    w: {},
    "": "hi"
};
```

```
var w = new Object();
w.x = "test";
w.y = 1234;
w.z = new Object();
w.w = new Object();
w[""] = "hi";
```

The code on the left-hand side has exactly the same result as the one on the right-hand side

Add/Get/Set/Remove A Property

We can dynamically modify an object after its creation

```
var obj = {
   1 : "Hello",
   "3": "Good",
   x: "JavaScript",
   foo: 101,
   bar: true,
   "" : null
};
obj["2"] = "World";  // *1 Add & Set
obj.foo = 202; // *5 Set
delete obj.bar; // *6 Remove
delete obj[""];
                  // *7 Remove
```

◆ ▶

```
var x = { a: 100 };
var y = { a: 100 };

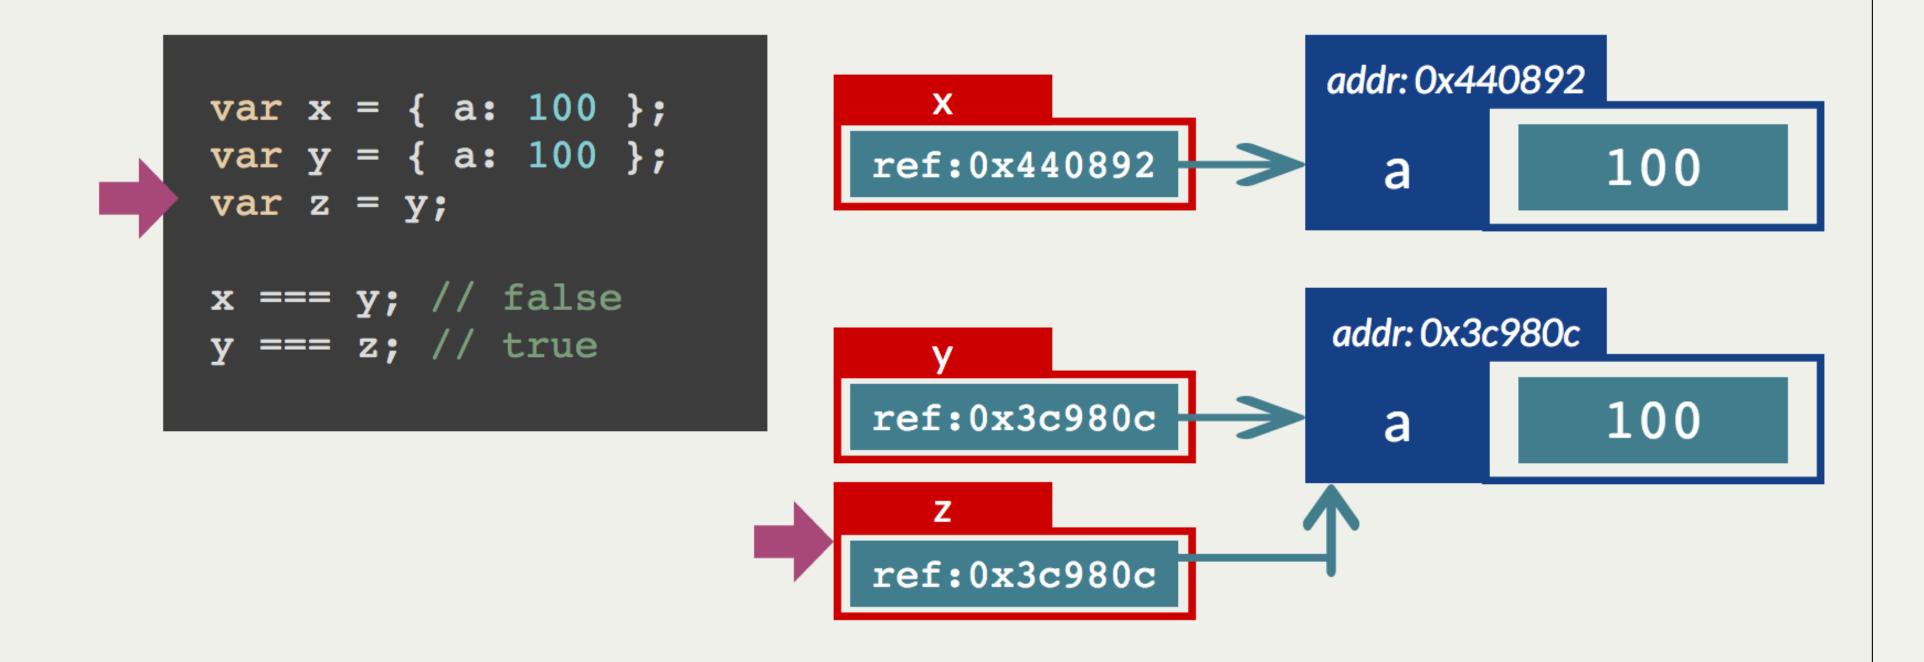

ref:0x440892

addr:0x440892

addr:0x3c980c

y
ref:0x3c980c
addr:0x3c980c
all 100
```

Similar to the "pointer" / "address" concept in programming languages like C or C++

```
var x = { a: 100 };
var y = { a: 100 };
var z = y;

x === y; // false
y === z; // true

y
ref:0x3c980c
z.a = 200;
z
ref:0x3c980c
z
```

```
var x = { a: 100 };
var y = { a: 100 };
var z = y;
x === y; // false
y === z; // true
z.a = 200;
x.a; // 100
y.a; // 200
z.a; // 200
```
